# **Glossary of Terms**

- ISU Iridium Subscriber Unit (e.g. SBD9602) on remote device (e.g. CTM200)
- MO Mobile Originated (e.g. MO messages are messages coming from remote device)
- MT Mobile Terminated (e.g. MT messages are messages sent to remote device)
- PAD Packet Assembly/Disassembly
- SQI Signal Quality Index (a relative measurement of signal quality)

# I. Overview

The Chameleon CTM-200 "Dual Mode" Gateway features an Iridium Subscriber Unit (ISU) satellite module (SBD9602) and a mini-PCI express/NGFF form factor cellular wireless module. With the internal ISU, **reports, cmd commands** and **Packet Assembly/Disassembly (PAD)** can all be sent via satellite.

Note: CTM-200 firmware 2.0.5.3356 and later is required

Note: Please ensure that the ISU is already provisioned with Iridium and can access their Iridium Gateway via email and/or direct IP. Please contact Cypress Solutions for more information.

• Remote configuration and control via cellular or satellite

Users should be aware of the benefits and limitations of using satellite. The table below shows a general comparison between satellite and cellular usage.

|                 | Satellite      | Cellular           |  |
|-----------------|----------------|--------------------|--|
| Coverage Global |                | Regional           |  |
| Bandwidth       | Low (bytes)    | High (Mbits)       |  |
| Latency         | High (minutes) | Low (milliseconds) |  |
| Cost/Byte       | \$\$\$         | \$                 |  |

Satellites offer greater terrestrial coverage than cellular, but have an associated higher cost. To minimize the data cost of satellite communications, CTM-200 has specific features to limit satellite traffic, which are described in this document.

It is also important for users to understand that typical reports configured for cellular transmission, such as the one shown below, might not be suitable for satellite transmission because of its limited data.

```
$PEVENT,153725.00,A,160713,356215040095550,GPS4:t>240*52[0x0D][0x0A]
$PGPS,153725.00,A,4915.4300,N,12259.8187,W,000.0,359.0,160713,+00021,10,356215040095550*7A[0x0D][0x0A]
$POBDA,A,p1=0,p2=0.00,p3=18,p4=5TEMU52N27Z410952,p7=0,p8=88,p22=31641,p14=0*0C[0x0D][0x0A]
$PPWR,12.59,0,40*3C[0x0D][0x0A]
```

CTM-200 offers some binary messages to help reduce data use, and hence, cost. Binary message are much more efficient, such as message #113 below which is similar to the \$PGPS message above. It uses only 37 bytes of data versus the 80+ bytes of the ascii message to transmit time, latitude, longitude, and modem ID.

[0x71][0x0C][0x06][0x00][0x00][0x1D][0x00][0x00][0xE4][0x67][0xE4][0x51][0xF1][0x28][0x4B][0x00][0x72][0x52] [0x44][0xFF][0xC0][0x00][0x33][0x35][0x36][0x32][0x31][0x35][0x30][0x34][0x30][0x34][0x31][0x30][0x31][0x30] [0x36]

## 2. Satellite message format

## 2.1 Format of messages sent from CTM-200

Messages sent from the CTM-200 (e.g. **reports**, **cmd command response**, **PAD**) are MO messages and can be sent in both email and direct IP (TCP) format. Please consult with your account provider to configure on Iridium's SPNet whether MO messages are to be sent via email or direct IP (TCP) or both.

### 2. I . I MO email message format

Messages arriving in email format will be similar to the following:

From: sbdservice@sbd.iridium.com To: <USER EMAIL> Subject: SBD Msg From Unit: <ISU'S IMEI> Attachment: <IMEI>\_<MO\_MSG\_SEQNUM>.sbd Body: MOMSN: <MO\_MSG\_SEQ\_NUM> MTMSN: <MT\_MSG\_SEQ\_NUM> Time of Session (UTC): <Date> Session Status: <STATUS> - Transfer <STATUS MSG> Message Size (bytes): <MO\_MSG\_SIZE>

Unit Location: Lat = <LATITUDE> Long = <LONGITUDE> CEPradius = <CEPRADIUS>

The payload of interest is contained in the .sbd attachment file, in raw binary format without any headers or additional info. **It can be up to 340 bytes.** The following is an example email and the contents of the accompanying attachment file (CTM-200 reports sent over satellite):

From: sbdservice@sbd.iridium.com To: kmo@cypress.bc.ca Subject: SBD Msg From Unit: 300234123412341 Attachment: 300234123412341\_000497.sbd

MOMSN: 497 MTMSN: 0 Time of Session (UTC): Wed Jul 17 00:12:59 2013 Session Status: 00 - Transfer OK Message Size (bytes): 105

Unit Location: Lat = 49.28267 Long = -123.01926 CEPradius = 8

300234123412341\_000497.sbd contains the following:

\$PIND,000000,0\*23 \$PINA,1,0.00\*39 \$GPRMC,232617.00,A,4915.4103,N,12259.7944,W,000.0,036.0,160713,,\*29

## 2. I.2 MO direct IP message format

Messages sent via TCP directly to a destination IP are of the following format:

|                                | Data Type        | Length (bytes) | Value                    |
|--------------------------------|------------------|----------------|--------------------------|
| Protocol Revision Number       | char             | 1              | 0x01                     |
| Overall Message Length         | unsigned short   | 2              | N+48                     |
| MO Header ID                   | char             | 1              | 0x01                     |
| MO Header Length               | unsigned short   | 2              | 0x1C                     |
| CDR Reference (Auto ID)        | unsigned integer | 4              | 0-4294967295             |
| IMEI                           | char             | 15             | ASCII numeric characters |
| Session Status                 | unsigned char    | 1              | 0,1,2,10,12-15           |
| MOMSN                          | unsigned short   | 2              | 1-65535                  |
| MTMSN                          | unsigned short   | 2              | 0-65535                  |
| Time of Session                | unsigned integer | 4              | Epoch time               |
| MO Location Information ID     | char             | 1              | 0x03                     |
| MO Location Information Length | unsigned short   | 2              | 0x0B                     |
| Latitude/Longitude             | double           | 7              | See table below          |
| CEP Radius                     | unsigned integer | 4              | 1-2000                   |
| MO Payload Header ID           | char             | 1              | 0x02                     |
| MO Payload Length              | unsigned short   | 2              | N (up to 340)            |
| MO Payload                     | char             | N (up to 340)  | Payload bytes            |

#### Latitude/Longitude format:

| MSBit LSBit                                 |     |   |   |         |   |       | LSBit   | Byte   | Description and Allowed Values                |
|---|-----|---|---|---------|---|-------|---------|--------|---|
| 0   | 1   | 2 | 3 | 4       | 5   | 6     | 7       | Number |   |
| Reser                                       | ved |   |   | Form    | nat                                       | NSI   | EWI     | 1      | Reserved & Format Code: 0                     |
|   |     |   |   | Code    |   |       |         |        | NSI: North/South Indicator (0=North, 1=South) |
|   |     |   |   |         | EWI: East/West Indicator (0=East, 1=West) |       |         |        |   |
| Latitude (degrees)                          |     |   |   |         |   | 2     | 0-90    |        |   |
| Latitude (thousandths of a minute, MSByte)  |     |   |   |         | ite, MS                                   | Byte) |         | 3      | 0-59999                                       |
| Latitude (thousandths of a minute, LSByte)  |     |   |   |         | ite, LSB                                  | yte)  |         | 4      |   |
| Longitude (degrees)                         |     |   |   |         |   |       |         | 5      | 0-180   |
| Longitude (thousandths of a minute, MSByte) |     |   |   | ISByte) | )   | 6     | 0-59999 |        |   |
| Longitude (thousandths of a minute, LSByte) |     |   |   | SByte)  |   | 7     |         |        |   |

The following is an example TCP message containing the same information as in 4.1.1's example:

[0x01][0x00][0x99][0x01][0x00][0x1C][0x04][0x88][0xF8][0xEE][0x33][0x30][0x30][0x32][0x33][0x34][0x31][0x32][0x33] [0x34][0x31][0x32][0x33][0x34][0x31][0x00][0x01][0xF1][0x00][0x00][0x00][0x51][0xE5][0xE1][0x88][0x03][0x00][0x08][0x01] [0x31][0x42][0x40][0x78][0x04][0x83][0x00][0x00][0x00][0x08][0x02][0x00][0x69][0x24][0x50][0x49][0x4E][0x44][0x2C] [0x30][0x30][0x30][0x30][0x30][0x30][0x2C][0x30][0x2A][0x32][0x33][0x0D][0x0A][0x24][0x50][0x49][0x4E][0x41][0x2C] [0x31][0x2C][0x30][0x2E][0x30][0x20][0x30][0x2A][0x33][0x0D][0x0A][0x24][0x47][0x50][0x52][0x40][0x43][0x2C][0x32] [0x33][0x22][0x36][0x31][0x37][0x2E][0x30][0x2C][0x41][0x2C][0x34][0x39][0x34][0x35][0x2E][0x34][0x31][0x30] [0x33][0x2C][0x4E][0x2C][0x31][0x32][0x32][0x35][0x39][0x2E][0x37][0x39][0x34][0x34][0x2C][0x57][0x2C][0x30] [0x30][0x2E][0x30][0x2C][0x33][0x36][0x2E][0x30][0x2C][0x31][0x36][0x37][0x31][0x33][0x2C][0x2A] [0x33][0x2C][0x30][0x2C][0x33][0x36][0x2E][0x30][0x2C][0x31][0x36][0x37][0x31][0x33][0x2C][0x2A] [0x33][0x2C][0x30][0x2C][0x33][0x36][0x2E][0x30][0x2C][0x31][0x36][0x37][0x31][0x33][0x2C][0x2A] [0x33][0x2C][0x30][0x2C][0x33][0x36][0x2E][0x30][0x2C][0x31][0x36][0x30][0x37][0x31][0x33][0x2C][0x2A] [0x33][0x2C][0x30][0x2C][0x33][0x36][0x2E][0x30][0x2C][0x31][0x36][0x30][0x32][0x32][0x32][0x32][0x33][0x32][0x33][0x30][0x2C][0x33][0x30][0x2C][0x33][0x30][0x2C][0x33][0x30][

## 2.2 Format of messages sent to CTM-200

Messages sent to the CTM-200 (e.g. **cmd commands, PAD**) are MT messages and can also be sent in email format. To prevent unauthorized users from sending messages over the satellite network, it is possible to restrict access to up to 10 emails and/or IPs. This prevents third parties from abusing the system and accruing data charges.

## 2.2. I MT email message format

Messages can be sent to the CTM-200 via email. Simply save the payload as the content of an attachment with extension **.sbd** and send the attachment to an Iridium Gateway, such as **data@sbd.iridium.com**, with the remote ISU's IMEI as the subject.

Note: Each attachment can only contain up to 270 bytes.

A sample email format is as follows:

From: kmo@cypress.bc.ca To: data@sbd.iridium.com Subject: 300234123412341 Attachment: msgtoctm200.sbd

The attachment msgtoctm200.sbd contains the payload to send to the CTM-200:

\$1cmd ver

## **3. Configuration Examples**

This section is intended to provide examples of commonly used satellite configurations. While satellite commands are listed in section 6, a complete list of commands can be found online at http://www.cypress.bc.ca/command\_reference.html.

Note: All configuration examples must end with a cmd save and cmd pwr mode 2 to take effect.

## 3. I Reporting over satellite

Reports can be sent over satellite by choosing **report type 10** for remote servers in **cmd reptype**, **cmd iorep** and **cmd gpsrep**.

Note: Local reports cannot be used with satellite reports for each specific report number

## 3. I. I Single report example

This example demonstrates how to configure a single report to report over satellite when the supply voltage is below 10V. The main satellite related commands to be concerned with are in the first 2 lines.

| cmd sat enable 1                         | <pre>// enable satellite // satellite type (10) and no local reports allowed</pre>             |
|--|--|
| cmd vcccond 1 1 10                       | <pre>// trigger Vcc cond #1 every 1m while Vcc is below 10V</pre>                              |
| cmd vccreport 1 1<br>cmd repaddmes 1 116 | <pre>// associate Vcc cond #1 to use report #1 // add message #116 (\$PPWR) to report #1</pre> |

If local reports are also required to be sent in addition to the satellite report, add a new local report based on the same triggering condition. Please note that this local report will not be limited by **cmd sat mt**, so it will be reporting whenever the triggering condition occurs.

| cmd sat enable 1     | // enable satellite  |   |
|----------------------|--|---|
| cmd reptype 1 0 10 0 | // satellite type (10) and no local reports allowed  |   |
| cmd reptype 2 3 0 0  | // local reporting over UDP - this will send every 1m because of vcccond below             |   |
| cmd vcccond 1 1 10   | <pre>// trigger Vcc cond #1 every 1m while Vcc is below the threshold voltage of 10V</pre> |   |
| cmd vccreport 1 1 2  | // associate Vcc cond #1 to use report #1 and report #2                                    |   |
| cmd repaddmes 1 116  | // add message #116 (\$PPWR) to report #1  |   |
| cmd repaddmes 2 116  | // add message #116 (\$PPWR) to report #2  |   |
|                      |  | 1 |

## 3.1.2 Satellite minimum time example

To help limit data use, **cmd sat mt** configures the minimum time between identical report numbers being sent over satellite. Reports generated before the minimum time is reached are discarded. If **cmd sat mt** is not configured, then the default of 10 minutes is used (**cmd sat mt 10**.)

This example demonstrates how 2 GPS triggered reports (GPS report 1 set to report every 1 min, and GPS report 2 set to report every 2 minutes) configured to report over satellite works. What is of interest here is that **cmd sat mt 3** is configured to limited GPS reports 1 and 2 to a minimum time of 3 minutes between each respective report.

| / |                     |  |
|---|---------------------|--|
|   | cmd sat enable 1    | // enable satellite  |
|   | cmd sat mt 3        | // set the minimum time between each identical report numbers to 3 min |
|   | cmd gpscond 1 1 60  | // GPS report 1 to trigger every 1m                                    |
|   | cmd gpscond 2 1 120 | // GPS report 2 to trigger every 2m                                    |
|   | cmd gpsrep 1 0 10 0 | // GPS report 1 to use satellite                                       |
|   | cmd gpsrep 2 0 10 0 | // GPS report 2 to use satellite                                       |
|   | cmd gpsaddmes 1 113 | // add binary message 113 to GPS report 1                              |
|   | cmd gpsaddmes 2 113 | // add binary message 113 to GPS report 2                              |
|   |                     |  |

The above configuration will result in the following behavior (last 2 columns are the final results):

| Time      | Rep 1     | Rep 2     | Time since | Time since | GPS Report 1 | GPS Report 2 |
|-----------|-----------|-----------|------------|------------|--------------|--------------|
| (minutes) | Triggered | Triggered | last rep 1 | last rep 2 | Result       | Result       |
| 1         | Y         |           | 0*         |            | SENT         |              |
| 2         | Y         | Y         | 1          | 0*         | DISCARDED    | SENT         |
| 3         | Y         |           | 2          |            | DISCARDED    |              |
| 4         | Y         | Y         | 3*         | 2          | SENT         | DISCARDED    |
| 5         | Y         |           | 1          |            | DISCARDED    |              |
| 6         | Y         | Y         | 2          | 4*         | DISCARDED    | SENT         |
| 7         | Y         |           | 3*         |            | SENT         |              |
| 8         | Y         | Y         | 1          | 2          | DISCARDED    | DISCARDED    |
| 9         | Y         |           | 2          |            | DISCARDED    |              |
| 10        | Y         | Y         | 3*         | 4*         | SENT         | SENT         |
| 11        | Y         |           | 1          |            | DISCARDED    |              |
| 12        | Y         | Y         | 2          | 2          | DISCARDED    | DISCARDED    |
| 13        | Y         |           | 3*         |            | SENT         |              |
| 14        | Y         | Y         | 1          | 4*         | DISCARDED    | SENT         |
|           |           |           |            |            |              |              |

\*First report or minimum time has been reached, so allowed to send

## 3. I.3 Failover handling example

Satellites can be used as an alternative should the primary reporting channel be disrupted. In this example, an I/O report is configured to report to a remote IP via TCP, with satellite as a failover option. It sets I/O reports 1 and 2 to be based on the same triggering condition, with I/O report 2, which is sent over satellite, only sent when CTM detects cell is down. Note that because **cmd sat mt** is not set, the default value of 10 min is used.

| cmd sat enable 2   | // dynamic mode                                  |
|--------------------|--|
| cmd iocond 1 1 60  | <pre>// generate I/O report #1 every 1 min</pre> |
| cmd iocond 2 1 60  | <pre>// generate I/O report #2 every 1 min</pre> |
| cmd iorep 1 0 5 0  | // remote TCP                                    |
| cmd iorep 2 0 10 0 | // satellite type                                |
| cmd ioaddmes 1 80  | // add message 80 to I/O report #1               |
| cmd ioaddmes 2 80  | // add message 80 to I/O report #2               |
|                    |  |

The above configuration will result in the following:

| Time (minutes) | Time since last I/O rep 2 | I/O Report 1 | I/O Report 2 |
|----------------|---------------------------|--------------|--------------|
| 1              | SAT POWERED OFF           | SENT         | DISCARDED    |
| CELL OFFLINE   | SAT POWERED ON            | -            | -            |
| 2              | 0*                        | NOT SENT     | SENT         |
| 3              | 1                         | NOT SENT     | DISCARDED    |
| 4              | 2                         | NOT SENT     | DISCARDED    |
| 5              | 3                         | NOT SENT     | DISCARDED    |
| 6              | 4                         | NOT SENT     | DISCARDED    |
| 7              | 5                         | NOT SENT     | DISCARDED    |
| 8              | 6                         | NOT SENT     | DISCARDED    |
| 9              | 7                         | NOT SENT     | DISCARDED    |
| 10             | 8                         | NOT SENT     | DISCARDED    |
| 11             | 9                         | NOT SENT     | DISCARDED    |
| 12             | 10*                       | NOT SENT     | SENT         |
| 13             | 1                         | NOT SENT     | DISCARDED    |
| 14             | 2                         | NOT SENT     | DISCARDED    |
| 15             | 3                         | NOT SENT     | DISCARDED    |
| 16             | 4                         | NOT SENT     | DISCARDED    |
| 17             | 5                         | NOT SENT     | DISCARDED    |
| 18             | 6                         | NOT SENT     | DISCARDED    |
| 19             | 7                         | NOT SENT     | DISCARDED    |
| 20             | 8                         | NOT SENT     | DISCARDED    |
| 21             | 9                         | NOT SENT     | DISCARDED    |
| 22             | 10*                       | NOT SENT     | SENT         |
| 23             | 1                         | NOT SENT     | DISCARDED    |
| CELL ONLINE    | SAT POWERED OFF           | -            | -            |
| 24             | SAT POWERED OFF           | SENT         | DISCARDED    |

\*First report or minimum time has been reached, so allowed to send

In the satellite failover handling case, when cell is down the MODE LED displays whether the ISU module is powered on and whether it is registered on the satellite network:

| ISU Module Status | ISU Module Registered on Network? | MODE LED Status                |
|-------------------|-----------------------------------|--------------------------------|
| OFF               | NO                                | OFF                            |
| ON                | NO                                | Blink once every second        |
| ON                | YES                               | Blink three times every second |

#### 3.1.4 On demand reporting over satellite example

It is also possible to send messages on demand over satellite while in failover/dynamic mode. This could be used with report triggered scripts for versatile reporting (e.g. turn ISU module on, send a report to satellite, then turn ISU module off, etc.)

Note: ON states have priority, meaning cmd sat pwr 1 and CTM's decision to turn ISU module ON in failover mode have priority.

In this example, I/O report 2 is sent on demand over satellite, even when there is a cellular connection:

| cmd sat enable 2   | // dynamic mode                                  |
|--------------------|--|
| cmd iocond 1 1 60  | <pre>// generate I/O report #1 every 1 min</pre> |
| cmd iocond 2 1 60  | <pre>// generate I/O report #2 every 1 min</pre> |
| cmd iorep 1 0 5 0  | // remote TCP                                    |
| cmd iorep 2 0 10 0 | // satellite type                                |
| cmd ioaddmes 1 80  | <pre>// add message 80 to I/O report #1</pre>    |
| cmd ioaddmes 2 80  | <pre>// add message 80 to I/O report #2</pre>    |
|                    |  |

The following two commands can be used to enable or disable satellite on the fly:

| cmd sat pwr 1 | // turn satellite ON  |
|---------------|-----------------------|
| cmd sat pwr 0 | // turn satellite OFF |

With the above commands, it is possible to do the following:

| Time (minutes) | Time since last I/O rep 2 | I/O Report 1 | I/O Report 2 |
|----------------|---------------------------|--------------|--------------|
| 1              | SAT POWERED OFF           | SENT         | DISCARDED    |
| CELL OFFLINE   | SAT POWERED ON            | -            | -            |
| 2              | 0*                        | NOT SENT     | SENT         |
| 3              | 1                         | NOT SENT     | DISCARDED    |
| CELL ONLINE    | SAT POWERED OFF           | -            | -            |
| 4              | SAT POWERED OFF           | SENT         | DISCARDED    |
| cmd sat pwr 1  | SAT POWERED ON            | -            | -            |
| 5              | 3                         | SENT         | DISCARDED    |
| 6              | 4                         | SENT         | DISCARDED    |
| 711            | 59                        | SENT         | DISCARDED    |

| 12            | 10*             | SENT | SENT      |
|---------------|-----------------|------|-----------|
| cmd sat pwr 0 | SAT POWERED OFF | -    | -         |
| 13            | SAT POWERED OFF | SENT | DISCARDED |

\*First report or minimum time has been reached, so allowed to send

#### Another example is if CTM is configured to report over satellite if an I/O's threshold is exceeded:

There may be situations where it is desirable to occasionally send a report over satellite. Because of its infrequency, the satellite module could be powered off most of the time, and only powered on to send a report. This could be accomplished in conjunction with report triggered scripts.

In this example, a CTM is configured to report over satellite if an input voltage exceeds a configured threshold voltage. It is expected that the input voltage does not typically exceed the threshold voltage during normal use, so these reports are supposed to be infrequent.

#### <u>Step 1:</u>

Configure the CTM to trigger a report (e.g. I/O report #1) that will run a script to check the input voltage. If the voltage is above the set threshold, the script will power ON the ISU module and send the desired report (e.g. I/O report #2). If the voltage is below the threshold, the script will power OFF the ISU module.

A sample configuration is as below:

| / |                         |   |  |
|---|-------------------------|---|--|
|   | cmd sat enable 2        | // dynamic mode   |  |
|   | cmd autoconnect 0       | // disable connecting to external cellular network to disable failover mode             |  |
|   | cmd reportscripts 1     | // enable report triggered scripts  |  |
|   | cmd insetup 1 A 7.5 P 2 | // set input #1 to trigger when measured voltage crosses 7.5V threshold                 |  |
|   | cmd iocond 1 1 60 1     | // generate I/O report #1 every 1 min if input #1 is triggered - used to trigger script |  |
|   | cmd iorep 2 0 10        | <pre>// set I/O report number #2 to use satellite type</pre>                            |  |
|   | cmd ioaddmes 2 21       | // add message 21 (\$PINA for input #1) to I/O report #2                                |  |
| / |                         |   |  |

#### <u>Step 2:</u>

Add the following into a file named report1040.sh (1040 corresponds to I/O report #1):

```
# Grab current input voltage
tVal=$( cmd input | awk 'NR==1' | awk -FV '{print $1}' )
# Grab threshold
tThreshold=$( cmd insetup | awk 'NR==1' | awk '{print $5}' )
# Compare decimal values
tRes=$( echo $tVal $tThreshold | awk '{ if ($1 > $2) print "1"; else print "0"}')
# Enable and send report or disable satellite based on comparison above
if [ $tRes -gt 0 ] ; then
cmd sat pwr 1
cmd sendreport 1041
else
cmd sat pwr 0
fi
```

SATELLITE SUPPORT

The previous script will check the input voltage when input #1 is triggered, and enable the ISU module and sent I/O report #2 (1041 corresponds to I/O report #2) if the input voltage is above the configured threshold, or disable the ISU module to save power.

#### <u>Step 3:</u>

Save the file in **/etc/reports/scripts** on the CTM and run the following two commands in CTM's console:

dos2unix report1040.sh chmod +x report1040.sh

#### <u>Step 4:</u>

Run **cmd save** as done for all configuration changes to save the script.

The previous setup will result in a behavior similar to the following:

| Time      | Input | I/O Report 1      | Greater than | ISU module | I/O Report 2 | Time since     | I/O Report 2  |
|-----------|-------|-------------------|--------------|------------|--------------|----------------|---|
| (minutes) | #1    | script triggered? | threshold?   | power      | triggered?   | last I/O rep 2 | Result  |
| 1         | 3V    |                   |              | OFF        |              |                |   |
| 2         | 8V    | Υ                 | Υ            | ON         | Υ            | 0              | SENT  |
| 3         | 8V    |                   |              | ON         |              |                |   |
| 4         | 8V    |                   |              | ON         |              |                |   |
| 5         | 3V    | Υ                 | Ν            | OFF        | Ν            |                |   |
| 6         | 3V    |                   |              | OFF        |              |                |   |

| N+3       | 4V    |                   |              | OFF        |              |                |   |

## 3. I.5 Man Down Pendant Panic reports over satellite example

Man Down pendant panic reports can also be sent over satellite. However, because panic (PANIC/MPANIC/FPANIC) reports are of high priority, these panic reports are handled differently than all other reports.

Panic reports are still restricted by **cmd sat mt**, but they are matched against a list of previous Man Down pendant IDs instead of a list of previous report numbers sent over satellite. That is, although all panic reports use the same report number set in **cmd panicreport**, panic reports are gated based on pendant ID to prevent one pendant's panic report from starting a **cmd sat mt** timer that bars a subsequent panic report from another pendant from being sent if the mt timer has not elapsed.

#### Note: cmd sat enable 1 should be used or sat force 1 if using sat enable 2

Note: Panic reports from the same Pendant will still be limited by **cmd sat mt**.

In this example, the CTM is configured to send Man Down Pendant panic messages over satellite. Two pendants are used in the field.

Note: **cmd wpan acktype** must be set to '**m**' (modem) because '**s**' (server) type acknowledgement is too slow over satellite.

| 1 |                                   |  |  |
|---|-----------------------------------|--|--|
| ( | cmd sat enable 1                  | // enable satellite  |  |
|   | cmd sat mt 2                      | // set minimum time between reports from the same pendant to 2 min     |  |
|   | cmd panicreport 1                 | // use general report #1 for sending PANIC/MPANIC/FPANIC messages      |  |
|   | cmd panicreptype 1                | <pre>// set panic report to be of binary type</pre>                    |  |
|   | cmd reptype 1 0 10                | // set general report #1 to use satellite type                         |  |
|   | cmd repaddmes 1 82                | <pre>// add message 82 (\$GPRMC) to general report #1</pre>            |  |
|   | cmd wpan stm 1                    | // use internal WPAN gateway   |  |
|   | cmd wpan adddev fffffffffffffffff | // allow all Man Down Pendants to connect to the internal WPAN gateway |  |
|   | cmd wpan acktype m                | <pre>// pendant acktype must be set to m</pre>                         |  |
| \ |                                   |  |  |

#### Note: cmd panicreptype 0 (default) will set the panic report to be ASCII (e.g.

\$PPEN, 0013A200402CB498, 17, PANIC\*07) while cmd panicreptype 1 will set the panic report to be binary (message #93).

The above configuration will result in a behavior similar to the following:

| Time      | Pendant 1 | Pendant 2 | Time since     | Time since     | Pendant 1 | Pendant 2 |
|-----------|-----------|-----------|----------------|----------------|-----------|-----------|
| (minutes) |           |           | last Pendant 1 | last Pendant 2 | Report    | Report    |
| 1         | PANIC     | PANIC     | 0*             | 0*             | SENT      | SENT      |
| 2         | MPANIC    | FPANIC    | 1              | 1              | DISCARDED | DISCARDED |
| 3         | FPANIC    | MPANIC    | 2*             | 2*             | SENT      | SENT      |

\*First report or minimum time has been reached, so allowed to send

## 3. I.6 Effect of message ordering while using ASCII Pendant Panic reports

If messages are added to ASCII Pendant panic reports (e.g. configured via **cmd panicreport, cmd panicreptype 0** is used, and extra messages added using **cmd repaddmes**), the message order and type becomes important because added messages may or may not be grouped with the panic report. Understanding this is significant because panic reports are checked against a list of previous Man Down Pendant IDs while all other reports are checked against a list of previous report numbers for **cmd sat mt** requirement.

When reports are generated and sent out, messages added to the reports are added first because they typically provide useful starting information such as IMEI/ESN, GPS location, etc. The actual report is (e.g. \$PPEN) then appended to the end of this group of added messages.

For example:

| MESSAGE I MESSAGE 2 MESSAGE 3 MESSAGE 4 MAIN MSG/REPORT |  |
|---|--|
|---|--|

In addition, to optimize transmitting data, consecutive ASCII messages are merged together into one message when possible. Binary messages are sent individually because they have their own ULCP header.

For example, **cmd repaddmes 1 3 82 112** adds two ASCII messages (message #3, \$PMID, and #82, \$GPRMC) and a binary message (message #112):

| #3 (A) #82 (A) #112 (B) - MAIN MSG/REP |
|--|
|--|

These message types will be represented as **A A B** for simplicity, where **A is ASCII** and **B is binary**. The first two ASCII messages will be merged together, effectively becoming only **A B**. ASCII message **A** (containing message #3 and #82) will be sent first, followed by binary message **B**:

| #3, #82 (A) | #112 (B) | - | MAIN MSG/REPORT |
|-------------|----------|---|-----------------|
|             |          |   |                 |

Another example is **cmd repaddmes 1 3 112 80 82**, which is represented by **A B A A**, effectively becoming **A B A**:

| #3 (A) #2 | ±112 (B) | #80, #82 (A) | MAIN MSG/REPORT |
|-----------|----------|--------------|-----------------|
|-----------|----------|--------------|-----------------|

The result is that message #3 is sent first, followed by message #112, then messages #80 and #82 are sent together.

Assuming the main panic report appended at the end of the group of messages is represented by P, the above example is represented by **A B A P**:

| #3 (A) | #112 (B) | #80, #82 (A) | MAIN MSG/REP (P) |
|--------|----------|--------------|------------------|
|        |          |              |                  |

However, because the main report is also an ASCII type, and ASCII messages are grouped together, it is further reduced down to  $A B A P \rightarrow A B A \rightarrow A B P$  (changed to P because it contains a panic report), where P contains the ASCII messages #80, #82 as well as the \$PPEN panic report:

| #3 (A) | #112 (B)        | #80. #82 (A). MAIN MSG/REP (A.P |
|--------|-----------------|---------------------------------|
|        | ··· = = = ( = ) |                                 |

The consequence is that the entire P message will be checked against the list of previous Man Down Pendant IDs, including message #80 and #82.

In short, the last group of ASCII messages will be grouped with the panic report:

| cmd | repaddmes A B A A |  |
|-----|-------------------|--|
|-----|-------------------|--|

| $(\Lambda)$ | (D) |                               |
|-------------|-----|-------------------------------|
| (A)         | (B) | (A)(A), WAIN WISG/REP $(A,P)$ |

| cmd repaddmes B A | ΑΑ                          |
|-------------------|-----------------------------|
| (B)               | (A) (A), MAIN MSG/REP (A,P) |

| cmd | repaddmes A A A B |   |
|-----|-------------------|---|
|     |                   | - |

(A) (A) (B) MAIN MSG/REP (A,P)

In all previous examples, **P** messages (orange) are checked against the list of previous Man Down Pendant IDs while yellow and green messages are checked against the list of previous report numbers. This can be used to control whether messages are to be sent with pendant panic reports or not.

Note: For each report number, messages generated within 5 seconds of the first message will all be allowed through to prevent messages of a group being filtered out by **cmd sat mt** being triggered by the first message.

#### Sending ASCII messages with ASCII pendant panic messages:

| cmd sat enable 1                  | // enable satellite  |
|-----------------------------------|--|
| cmd sat mt 2                      | // set minimum time between reports from the same pendant to 2 min         |
| cmd panicreport 1                 | // use general report #1 for sending PANIC/MPANIC/FPANIC messages          |
| cmd panicreptype 0                | // set panic report to be of ascii type                                    |
| cmd reptype 1 0 10                | <pre>// set general report #1 to use satellite type</pre>                  |
| cmd repaddmes 1 82                | // add message #82 (\$GPRMC) to general report #1 to show pendant location |
| cmd wpan stm 1                    | // use internal WPAN gateway   |
| cmd wpan adddev fffffffffffffffff | // allow all Man Down Pendants to connect to the internal WPAN gateway     |
| cmd wpan acktype m                | // pendant acktype must be set to m  |
|                                   |  |

This setting will result in the following (blue for checked against report number, green for Pendant ID):

| Time (minutes) | Pendant 1 | Pendant 2 | Pendant 1 Panic Report | Pendant 2 Panic Report |
|----------------|-----------|-----------|------------------------|------------------------|
| 1              | PANIC     | PANIC     | MSG 82+\$PPEN SENT     | MSG 82+\$PPEN SENT     |
| 2              | MPANIC    | FPANIC    | DISCARDED              | DISCARDED              |
| 3              | FPANIC    | MPANIC    | MSG 82+\$PPEN SENT     | MSG 82+\$PPEN SENT     |

#### Sending mix of binary and ASCII messages with ASCII pendant panic messages:

| / |                                   |  |  |
|---|-----------------------------------|--|--|
|   | cmd sat enable 1                  | // enable satellite  |  |
|   | cmd sat mt 2                      | // set minimum time between reports from the same pendant to 2 min     |  |
|   | cmd panicreport 1                 | // use general report #1 for sending PANIC/MPANIC/FPANIC messages      |  |
|   | cmd panicreptype 0                | // set panic report to be of ascii type                                |  |
|   | cmd reptype 1 0 10                | // set general report #1 to use satellite type                         |  |
|   | cmd repaddmes 1 82 113            | // add message #82 (\$GPRMC) and #113 to show pendant location         |  |
|   | cmd wpan stm 1                    | // use internal WPAN gateway   |  |
|   | cmd wpan adddev fffffffffffffffff | // allow all Man Down Pendants to connect to the internal WPAN gateway |  |
|   | cmd wpan acktype m                | // pendant acktype must be set to m                                    |  |
|   |                                   |  |  |

This setting will result in the following (blue for checked against report number, green for Pendant ID):

| Time (minutes) | Pendant 1 | Pendant 2 | Pendant 1 Panic Report | Pendant 2 Panic Report            |
|----------------|-----------|-----------|------------------------|-----------------------------------|
| 1              | PANIC     |           | MSG 82+113+\$PPEN SENT |                                   |
| 2              |           | FPANIC    |                        | MSG 82+113 DISCARDED, \$PPEN SENT |
| 3              | FPANIC    | MPANIC    | MSG 82+113+\$PPEN SENT | MSG 82+113 SENT, \$PPEN DISCARDED |
| 4              |           |           |                        |                                   |
| 5              | PANIC     | PANIC     | MSG 82+113+\$PPEN SENT | MSG 82+113+\$PPEN SENT            |

In this example Pendant 1 generates a PANIC message at time=1. Because binary message 113 was injected between ASCII message 82 and the main \$PPEN panic message, messages 82 and 113 are both checked based on their report number. As it is the first time they are sent, they are allowed through. The \$PPEN message is also allowed through as it is the first time Pendant 1 sent a panic message.

At time=2, Pendant 2 generates a panic message. Like before, messages 82 and 113 are checked based on their report number. However, as Pendant 1 sent messages 82 and 113 less than mt minutes ago, the newly generated messages 82 and 113 by Pendant 2 will be discarded. Note that the \$PPEN message is allowed through as it is the first time Pendant 2 sent a panic message.

At time=3, Pendants 1 and 2 both generate a panic message. Since messages 82 and 113 were sent at time=1, which is mt minutes ago, messages 82 and 113 are allowed to be sent again. The \$PPEN message for Pendant 1 is also allowed through as Pendant 1's previous \$PPEN message was mt minutes ago. Note that while the \$PPEN message for Pendant 2 is discarded because Pendant 2 just sent a panic message 1 minute ago, messages 82 and 113 generated by Pendant 2 are sent because they were generated within 5 seconds of messages 82 and 113 generated by Pendant 1.

At time=4, nothing was generated.

At time=5, both Pendants sent a panic message. Messages 82 and 113 from Pendants 1 and 2 are generated within 5 seconds of each other, so they are both allowed through. \$PPEN messages for Pendants 1 and 2 are also both allowed through because 2 minutes or more have elapsed since the last \$PPEN message for both Pendants 1 and 2.

#### Sending mix of binary and ASCII messages with ASCII pendant panic messages (re-arranged):

| / |                                   |   |  |
|---|-----------------------------------|---|--|
|   | cmd sat enable 1                  | // enable satellite   |  |
|   | cmd sat mt 2                      | // set minimum time between reports from the same pendant to 2 min          |  |
|   | cmd panicreport 1                 | // use general report #1 for sending PANIC/MPANIC/FPANIC messages           |  |
|   | cmd panicreptype 0                | // set panic report to be of ascii type                                     |  |
|   | cmd reptype 1 0 10                | <pre>// set general report #1 to use satellite type</pre>                   |  |
|   | cmd repaddmes 1 3 113 82          | // add message #3 (\$PMID), #113 and #82 (\$GPRMC) to show pendant location |  |
|   | cmd wpan stm 1                    | // use internal WPAN gateway  |  |
|   | cmd wpan adddev fffffffffffffffff | // allow all Man Down Pendants to connect to the internal WPAN gateway      |  |
|   | cmd wpan acktype m                | // pendant acktype must be set to m   |  |
|   | ,                                 |   |  |

This setting will result in the following (blue for checked against report number, green for Pendant ID):

| Time (minutes) | Pendant 1 | Pendant 2 | Pendant 1 Panic Report   | Pendant 2 Panic Report   |
|----------------|-----------|-----------|--------------------------|--------------------------|
| 1              | PANIC     |           | MSG 3+113+82+\$PPEN SENT |                          |
| 2              |           | FPANIC    |                          | MSG 3+113 DISCARDED      |
|                |           |           |                          | MSG 82+\$PPEN SENT       |
| 3              | FPANIC    | MPANIC    | MSG 3+113+82+\$PPEN SENT | MSG 3+113 SENT           |
|                |           |           |                          | MSG 82+\$PPEN DISCARDED  |
| 4              |           |           |                          |                          |
| 5              | PANIC     | PANIC     | MSG 3+113+82+\$PPEN SENT | MSG 3+113+82+\$PPEN SENT |

This example is similar to the previous one, except that message 82 is last in **cmd repaddmes**, so it is now merged with \$PPEN messages. The result is that it is checked with \$PPEN messages against Pendant ID instead of report number. Message 3 is also checked based on report number because there is a binary message (message 113) between ASCII messages 3 and 82.

#### Sending mix of binary and ASCII messages with binary pendant panic messages (panicreptype 1):

If **cmd panicreptype is 1**, instead of an ASCII \$PPEN message, a binary message 93 is generated. The result is that all added message are checked based on report number and only binary message 93 is checked against Pendant ID. This is because binary message are not packaged together like ASCII messages are.

| 1 |                                   |  |  |
|---|-----------------------------------|--|--|
| ( | cmd sat enable 1                  | // enable satellite  |  |
|   | cmd sat mt 2                      | // set minimum time between reports from the same pendant to 2 min     |  |
|   | cmd panicreport 1                 | // use general report #1 for sending PANIC/MPANIC/FPANIC messages      |  |
|   | cmd panicreptype 1                | // set panic report to be of binary type                               |  |
|   | cmd reptype 1 0 10                | <pre>// set general report #1 to use satellite type</pre>              |  |
|   | cmd repaddmes 1 82 113            | // add message #82 (\$GPRMC) and #113 to show pendant location         |  |
|   | cmd wpan stm 1                    | // use internal WPAN gateway   |  |
|   | cmd wpan adddev fffffffffffffffff | // allow all Man Down Pendants to connect to the internal WPAN gateway |  |
|   | cmd wpan acktype m                | // pendant acktype must be set to m                                    |  |
|   |                                   |  |  |

SATELLITE SUPPORT

| Time (minutes) | Pendant 1 | Pendant 2 | Pendant 1 Panic Report | Pendant 2 Panic Report        |

| 2              |           | FPANIC    |                        | MSG 82+113 DISCARDED, 93 SENT |
| 3              | FPANIC    | MPANIC    | MSG 82+113+93 SENT     | MSG 82+113 SENT, 93 DISCARDED |
| 4              |           |           |                        |                               |
| 5              | PANIC     | PANIC     | MSG 82+113+93 SENT     | MSG 82+113+93 SENT            |

This setting will result in the following (blue for checked against report number, green for Pendant ID):

## **3.2** Sending commands over satellite

It is possible to send CTM commands via satellite (see section 4.2.) However, due to the nature of satellites, expect delays in transmission and response times of a few minutes. Only **sat enable 1/2** is required as **sat mt** is ignored.

There are two types of commands that can be sent over satellite:

| \$0cmd | // commands that do not require the response to be sent back to the sender |
|--------|--|
| \$1cmd | // commands that requires the response to be sent back to the sender       |

Any CTM command can be appended after \$0/\$1 except for the following commands, which are ignored:

## 3.2. I Send commands without expecting a response

Commands without needing a response should be sent with the following format:

The first two characters of the message must be **\$0**, followed by the CTM command. Multiple commands separated by semicolon ";", <**CR**> or <**LF**> can be sent in a single message.

For example, to enable CAN, save and power cycle the CTM, send either of the following command (see section 4.2 for more info on how to send messages to CTM-200 over satellite):

\$0cmd can prot 1;cmd save;cmd pwr mode 2

\$0cmd can prot 1[0x0A]cmd save[0x0D]cmd pwr mode 2

### 3.2.2 Send commands expecting a response

Commands needing a response should be sent with the following format:

#### \$1[command]

The first two characters of the message must be **\$1**, followed by the CTM command. Multiple commands separated by semicolon ";", <**CR**> or <**LF**> can be sent in a single message.

For example, to query the current CAN settings of a CTM, send the following command (see section 4.2 for more info on how to send messages to CTM-200 over satellite):

\$1cmd can show

The CTM's CAN settings should arrive via email or direct IP within a few minutes.

Note: Because the response is greater than 340, it was split over 2 emails/attachments). Also notice how configured reports are also sent in the same payload (second attachment) for efficiency.

md can psthrumin 1 1 cmd can psthrumin 2 1 cmd can psthrumin 3 1 cmd can psthrumin 4 1 cmd can psthrumin 5 1 cmd can psthrumin 6 1 cmd can psthrumin 7 1 cmd can psthrumin 8 1 cmd can qryrate 2 \$PMID,356215040410106,356215040410106\*10 \$GPGGA,175900.00,4915.4096,N,12259.7949,W,1,12,00.7,+00028,M,,M,,0000\*6D

## 3.3 Transferring raw data or using PAD over satellite

It is possible to send raw data transferred over satellite with the CTM to a destination TCP server. As such, it is also possible to use PAD with satellite. Please note that **cmd sat mt** is ignored.

#### To send data transferred over satellite, use the following configuration:

| cmd sat enable 1           | // enable satellite                                       |
|----------------------------|---|
| cmd sat pad 1              | // enable raw/PAD data connection                         |
| cmd sat ip 123.123.123.123 | // remote IP to forward data received over satellite to   |
| cmd sat port 12345         | // remote port to forward data received over satellite to |

#### If using CTM's PAD server, set sat ip to local IP (not 127.0.0.1), sat port to pad port, and PAD TCP server:

| cmd sat enable 1       | // enable satellite  |   |
|------------------------|--|---|
| cmd sat pad 1          | // enable raw/PAD data connection  |   |
| cmd sat ip 192.168.1.1 | // local IP to send to PAD ps  |   |
| cmd sat port 12345     | // must be same as cmd pad port  |   |
| cmd pad port 12345     |  |   |
| cmd pad mode 1         | // configure CTM as a PAD TCP server   |   |
| cmd pad fwdl 340       | // set it to forward data after 340 bytes have been reached as that is maximum |   |
|                        | payload per packet for satellite   |   |
|                        |  | 1 |

The above configuration will allow devices to communicate with each other over a mix of serial/IP and satellite. For example, a device connected to CTM via serial or IP talking to a remote device connected to an Iridium Gateway.

# 4. Satellite Commands

## 4. I Command: sat enable m

sat enable [m]

| m | Description   |
|---|---|
| 0 | Satellite DISABLED and POWERED OFF (DEFAULT)                            |
| 1 | Satellite ENABLED and POWERED ON  |
| 2 | Dynamic mode (used with sat pwr, default state is DISABLED/POWERED OFF) |

For any features to use satellite, it must be enabled with m=1 or m=2 (dynamic mode). In dynamic mode, the satellite ISU is powered OFF until the CTM detects that it can no longer report via regular channels (e.g. cell/wifi), at which point the ISU is turned ON. It is also controlled by the command **cmd sat pwr** in dynamic mode.

## 4.2 Command: sat mt t

sat mt [t]

| t          | Description                          |
|------------|--------------------------------------|
| 0 to 65535 | Minimum time in minutes (DEFAULT 10) |

Sets the minimum time in minutes between reports sent via satellite for **identical report numbers** and **identical Man Down Pendant IDs.** This command is used to throttle the amount of data being sent over satellite. It affects **reports** only (i.e. commands and PAD are unaffected.)

# Note: If for some reason the CTM cannot connect to the satellite, outbound messages will be queued and sent once connection has been established. If enough messages have been queued, there is a potential "burst" of data at that time.

For example, if general report 1 is sent via satellite at time time to next time another report 1 is allowed to be sent via satellite is after time t+mt. Any report 1 generated between that time is discarded.

Since Man Down Pendants share the same report number configured in **cmd panicreport**, Man Down Pendants are tracked based on their IDs.

For example, if pendant 1 sends a panic message (PANIC/FPANIC/MPANIC) at time **t**, any other pendant with a different ID (e.g. pendant 2) can send a panic message **within t+mt** time, while the next panic message from pendant 1 allowed through **is after t+mt**. Panic messages generated before **mt** time has elapsed are discarded.

## 4.3 Command: sat pwr m

sat pwr [m]

|   | Description   |
|---|---|
| 0 | Satellite <b>DISABLED</b> and <b>POWERED OFF</b> ( <b>DEFAULT</b> ) |
| 1 | Satellite ENABLED and POWERED ON                                    |

When the satellite ISU is configured for dynamic mode (**cmd sat enable 2**), it can also be manually enabled and disabled using this command for on demand reporting. This command is volatile, so the state is not saved with **cmd save**.

Note: **ON** states have priority, meaning **cmd sat pwr** cannot override decisions made by CTM-200 in failover mode and turn the satellite module OFF, and vice versa (failover mode cannot power off the satellite module if **cmd sat pwr 1**.)

## 4.4 Command: sat force 📻

sat force [n]

| n | Description  |
|---|--|
| 0 | No message type will force satellite ISU to power ON         |
| 1 | Pendant's PANIC message will force ISU to power ON (DEFAULT) |

Bitmapped value selecting what type of message will force satellite ISU to power ON. Used with **cmd sat enable 2**. Pendant PANIC message is **ON by default** to ensure Pendant PANIC messages are sent out.

# 4.5 **Co**mmand: sat ip iii.iii.iii.iii

sat ip [iii.iii.iii.iii]

| iii.iii.iii.iii            | Description  |
|----------------------------|--|
| 0.0.0.0 to 255.255.255.255 | Remote IP address in decimal (DEFAULT 192.168.1.1) |

Transfers raw data (e.g. PAD) received over satellite to this IP. Also connects to this IP to receive messages to send over satellite. Uses TCP. **cmd sat pad must be set to 1**.

Note: If using with CTM's PAD, users must configure CTM's PAD server as TCP PAD server (**cmd pad mode 1**) and must use a local Ethernet IP (e.g. 192.168.1.1) and not 127.0.0.1.

## 4.6 Command: sat port n

sat port [n]

| n          | Description                                    |
|------------|--|
| 0 to 65535 | Remote port address in decimal (DEFAULT 23002) |

Used with command cmd sat ip, which sets the server's port, and cmd sat pad, to enable the function.

Note: If using CTM's PAD, users must set **cmd sat port** equal to **cmd pad port**.

## 4.7 Command: sat pad n

sat pad [n]

| n | Description                                      |
|---|--|
| 0 | Do not connect to server (DEFAULT)               |
| 1 | Connect to server at cmd sat ip and cmd sat port |

Enables or disables connecting to the configured destination server (e.g. raw data server or PAD server) via **cmd sat ip** and **cmd sat port**.

## 4.8 Command: sat stats

sat stats

Shows the current transmission count in bytes, signal quality index (SQI), registration and IMEI. The SQI has a range of 0 to 5, and each increment represents approximately 2dB improvement in link margin over the previous value. SQI=0 is at or below the minimum receiver sensitivity level, 1 is 2dB of link margin, and 5 is 10dB or more link margin. Please note that these are not calibrated output and only provides relative information about the receive signal, and not an absolute receiver level or a calibrated signal to noise ratio.

## 4.9 Command: sat flush

sat flush

Clears messages queued for transmission over satellite. This requires cmd ctm15x to be executed first.

## 4.10 Command: sat reset

sat reset

Resets the satellite transmission byte count. This requires cmd ctm15x to be executed first.
